

What to Do When Your Ring Camera Loses WiFi Connection

A [Ring camera going offline](#) is one of the most common headaches for smart home owners, but it rarely means the device itself is broken. In most cases, something changed on the network side — a new router, an updated password, or a weak signal — and the camera simply hasn't caught up yet.

The fastest fix is usually right inside the Ring app. Open the Devices menu, select the offline camera, and check its Device Health tile for a "Reconnect to WiFi" option. Entering your current network name and password here resolves the majority of cases within a couple of minutes.

One detail that trips up a lot of people: most Ring cameras only work on 2.4GHz WiFi, not 5GHz. If your router broadcasts both bands under the same name, your camera may be searching for a signal it simply can't see, even though every other device in the house connects fine.

If reconnecting through the app doesn't work, a manual reset using the setup button on the camera clears its old network settings entirely, letting you set it up fresh. This solves most remaining cases, especially after a full router replacement.

Keeping your home network stable — consistent passwords, updated router firmware, and cameras placed within solid signal range — goes a long way toward avoiding repeat disconnections altogether.
